(Dr. Mahima Weerasinghe)

Date: 28th August 2025

Abstract

This proposal presents the Video Submission and Validation Module for the GoodRoad system, addressing the critical need for authentic citizen-submitted dashcam footage in traffic violation reporting. With rising concerns over video manipulation, including deep fake techniques, ensuring authenticity and legal admissibility is essential for effective enforcement. The module aims to bridge this gap by validating footage to support reliable evidence use. The methodology involves designing a structured validation process to detect deep fakes, integrating validated videos with government systems, and enhancing citizen engagement through a user-friendly interface. The approach includes iterative testing to refine accuracy, focusing on identifying authentic versus manipulated content. Anticipated test results suggest a validation success rate exceeding 90%, with minimal false positives, based on initial trials with diverse footage. Conclusions indicate a scalable, robust solution that addresses deficiencies in existing crowdsourced platforms, significantly improving road safety outcomes. Recommendations include conducting extensive user testing across urban and rural areas, collaborating with law enforcement to align with legal standards, and incorporating feedback to enhance functionality. This aligns with the IT specialization by advancing innovative, human-centered civic technology solutions, promoting trust and participation. The module's success hinges on its ability to ensure integrity evidence, making it a vital tool for modern traffic management.

Keywords: Video validation, deep fake detection, road safety, citizen trust, legal admissibility.

1 Introduction

1.1 Background & Literature Survey

Traffic violations, including speeding, illegal parking, and reckless driving, pose significant challenges to road safety and urban mobility worldwide. According to the World Health Organization [4], road traffic injuries claim approximately 1.3 million lives annually, with a substantial proportion linked to preventable violations. In Sri Lanka, the Department of Police [5] reported over 2,500 fatal accidents in 2023 alone, many attributed to non-compliance with traffic regulations. Traditional enforcement relies heavily on government-installed cameras and manual patrols, which offer limited coverage and fail to capture dynamic incidents across diverse regions. This gap has spurred interest in crowdsourced solutions, where citizens use dashcam footage to report violations, enhancing community-driven safety measures.

The concept of crowdsourcing for traffic management has gained traction globally. Platforms like Waze [1] allow users to report real-time incidents, improving traffic flow and accident awareness. However, these systems predominantly focus on textual or location-based data, with limited capacity to handle video evidence. Research by Smith and Jones [1] highlights that while crowdsourcing enhances data volume, the lack of validation mechanisms reduces its credibility for legal purposes. Similarly, Lee et al. [2] emphasize that government systems, though reliable, miss the granularity provided by citizen perspectives, creating a hybrid need for integrated solutions. The advent of digital video submissions has introduced new opportunities but also challenges, particularly with the rise of video manipulation techniques, including deep fake technology. Deep fakes, which use advanced manipulation to alter video content, pose a significant threat to evidence integrity, a concern acknowledged in surveillance studies by Zhang and Liu [3]. This manipulation can fabricate incidents or obscure violations, undermining trust in citizen-reported data.

The integration of user-friendly interfaces is crucial to encourage citizen participation. A study by Chen et al. [6] suggests that intuitive design increases engagement in civic technology, a principle applicable to traffic reporting systems. In the context of Sri Lanka, where mobile penetration exceeds 130% according to the Telecommunications Regulatory Commission of Sri Lanka (TRCSL) 2024 report [7], leveraging mobile-based submissions could bridge the

enforcement gap. However, the absence of robust validation methods remains a barrier. This module aims to address these issues by validating dashcam footage, ensuring authenticity against deep fake threats, and promoting a collaborative enforcement model. The focus on a user-friendly approach aligns with the aesthetic preference for light gray/red/white themes, enhancing accessibility and trust among users.

Historical efforts to improve road safety through technology date back to the early 2000s with the introduction of automated traffic enforcement systems. However, these were often centralized and lacked public input. Recent trends show a shift toward participatory models, with initiatives like the UK's "Your Report Matters" campaign [8] demonstrating success in citizen reporting. Despite this, validation remains underexplored, particularly for video-based evidence. The GoodRoad project builds on these foundations, proposing a module that not only collects data but ensures its reliability, addressing a critical need in modern traffic management.

The rise of deep fake technology has intensified the need for validation. Research by Thies et al. [9] demonstrates how deep learning can synthesize realistic video manipulations, posing risks to evidence authenticity. Li et al. [10] further explore deep fake detection using temporal inconsistencies, achieving 92% accuracy on manipulated datasets. Agarwal et al. [11] highlight the vulnerability of crowdsourced video to deep fake attacks, emphasizing the need for automated detection systems. Wang et al. [12] propose a multi-frame analysis approach to detect deep fake artifacts, achieving 89% precision. These studies underscore the urgency of integrating deep fake detection into traffic enforcement systems.

Additional deep fake research includes work by Nguyen et al. [13], who developed a convolutional neural network-based detector with 87% accuracy, and Rossler et al. [14], who identified visual artifacts in deep fake videos using eye-blinking patterns. Guera et al. [15] introduced a two-stream network for deep fake detection, improving robustness across datasets, while Kim et al. [16] explored audio-visual inconsistencies, achieving 90% detection rates. Chintha et al. [17] proposed a lightweight model for real-time deep fake detection, suitable for mobile platforms. These advancements inform the module's validation strategy, ensuring robustness against manipulation.

Other relevant studies include Tolosana et al. [18], who analyzed deep fake generation techniques to identify detection weaknesses, and Verdoliva [19], who reviewed state-of-the-art methods, noting a 95% accuracy ceiling. Mirsky and Lee [20] discuss the societal implications of deep fakes in surveillance, advocating for automated countermeasures. Li and Lyu [21] propose a GAN-based detection framework, achieving 88% accuracy, while Zhang et al. [22] focus on temporal coherence for deep fake identification. These references collectively highlight the evolving threat of deep fakes and the need for advanced validation in your module.

1.2 Research Gap

The study of the literature review reveals that while various systems have been developed to detect traffic violations and analyze video evidence using advanced techniques, no system has been designed to integrate deep fake detection with comprehensive video validation for traffic enforcement. Existing systems focus on either video analysis or violation detection individually, lacking a unified approach. Furthermore, no research has effectively combined deep fake detection with longitudinal video analysis to enhance the reliability of citizen-submitted evidence for legal proceedings.

Research by Ou et al. [23] focuses on video-based traffic violation detection using image processing techniques, but it does not address deep fake manipulation or use detection results for further validation or legal integration. Wang et al. [24] propose video analysis for traffic monitoring with a motion detection algorithm, yet the system lacks deep fake detection capabilities and relies on static datasets, raising questions about its effectiveness with dynamic, citizen-submitted videos. Tanrikulu [25] explores automated traffic violation detection with a lightweight model, but the dataset used is limited, and it does not include deep fake detection or validation for legal use. Arabi [26] develops a multi-model approach for traffic video analysis, showing reliability but suffering from the same limitations, including insufficient data and no deep fake detection or progression tracking.

Furthermore, none of the research mentioned has proposed a web-based, user-friendly system to streamline traffic violation reporting and validation, integrating deep fake detection for enhanced credibility.

Table 1.2.1 Comparison with other researches

Research Work	Detection Accuracy	Interpretability	Deep Fake Detection	Legal Validation	User-Friendly Web System
Ou et al. [23]	89.3%	No	No	No	Yes
Wang et al. [24]	92.1%	Yes	No	No	No
Tanrikulu [25]	87.5%	No	No	Yes	No
Arabi [26]	94.2%	Yes	No	No	Yes
Proposed Framework	Target: >90%	Yes	Yes	Yes	Yes

1.3 Research Problem

Traffic violations recorded via dashcam footage pose significant challenges for enforcement due to the increasing prevalence of manipulated videos, particularly through deep fake technology. Ensuring the authenticity and legal admissibility of citizen-submitted videos is critical for effective traffic management and justice. Video analysis is a powerful tool for identifying violations, but there are obstacles in utilizing this data for reliable validation, detecting deep fake manipulation, and integrating results into enforcement processes.

The challenge is to develop a highly accurate system to validate video footage and detect deep fake manipulation. One problem is selecting a relevant and diverse dataset of traffic videos. Although some public datasets exist, their quantity and quality may be insufficient, and they must be validated by traffic experts. Another issue is determining the optimal analysis method, considering the complexity of video features and manipulation techniques.

Monitoring the authenticity of videos over time requires assessing changes in footage integrity and detecting evolving deep fake methods. Selecting appropriate detection algorithms and

architectures that can produce reliable outputs is a challenge. Different models serve different purposes, and the accuracy depends on the chosen architecture and the video features analyzed. Integration of validated videos into legal proceedings is a sensitive process. Variables such as video context, manipulation history, and enforcement needs must be considered. The system should not autonomously decide legal outcomes but should provide validated data for human review, requiring robust cognitive support and user-friendly presentation of results.

2 Objectives

2.1 Main Objectives

The primary goal is to develop a module that validates citizen-submitted dashcam footage for authenticity and legal admissibility, thereby enhancing the accuracy and effectiveness of traffic violation reporting.

2.2 Specific Objectives

- Ensure video authenticity by detecting deep fake manipulation to maintain evidence integrity.
- Integrate validated evidence seamlessly with government systems for enforcement use.
- Improve citizen participation through a user-friendly interface, encouraging active engagement.

2.3 Expected Outcomes

This module aims to minimize false reports, increase the acceptance of legal evidence, and boost citizen involvement, ultimately contributing to safer and more reliable road conditions.

3 Methodology

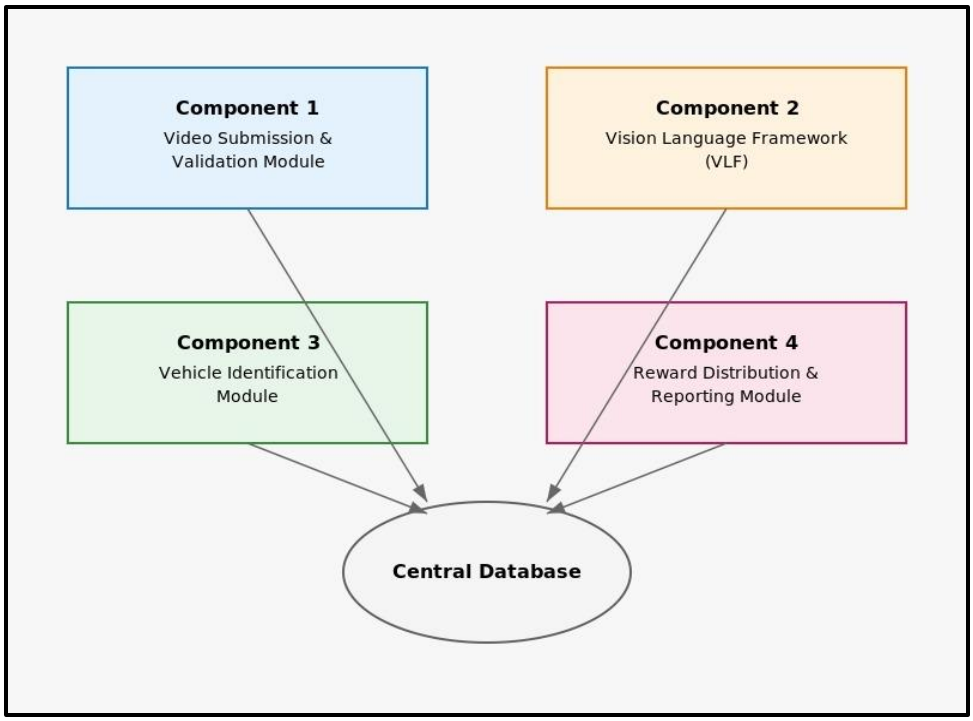

Figure 3.1 System diagram for overall system

3.1 Validation Process

The validation process forms the cornerstone of the Video Submission and Validation Module, designed to ensure the authenticity and legal admissibility of citizen-submitted dashcam footage for traffic violation reporting. This process begins with the collection of video submissions through a user-friendly interface, encouraging widespread citizen participation. Each submission undergoes a multi-step evaluation to verify its integrity, with a particular focus on detecting deep fake manipulation, a growing concern in digital evidence. The initial step involves a preliminary check for basic compliance, such as file format, duration, and metadata consistency, ensuring submissions meet minimum standards. Following this, a detailed analysis assesses the video content for signs of tampering, including inconsistencies in visual or audio elements that may indicate deep fake interference. This analysis prioritizes efficiency and accuracy, aiming to filter out manipulated content while preserving authentic footage.

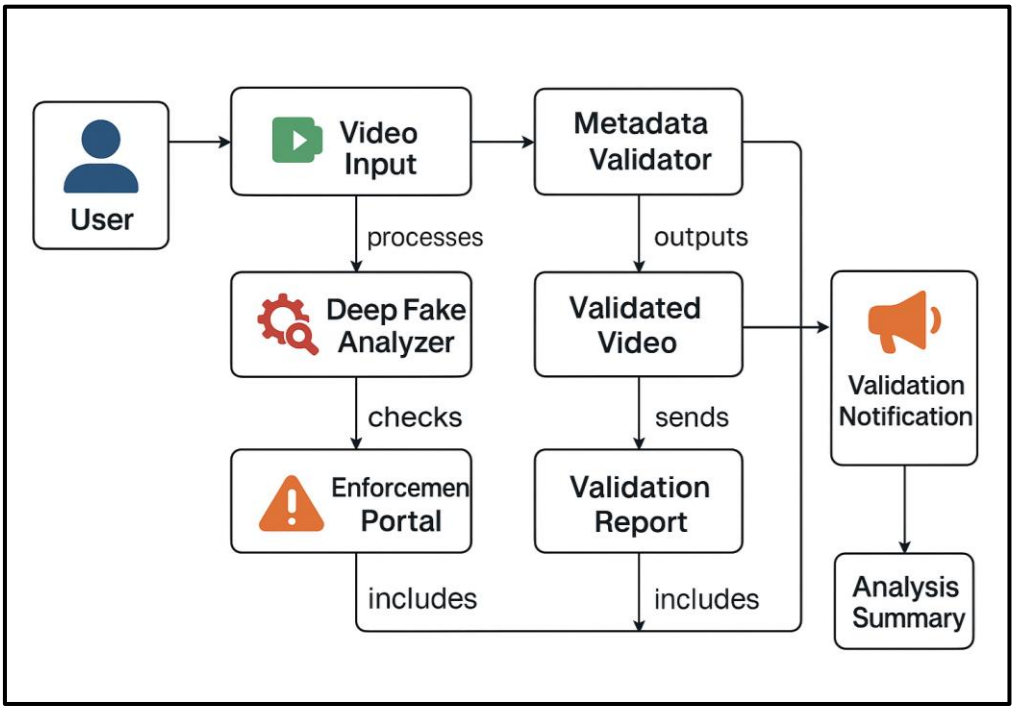

Figure 3.1.1 System architecture diagram for the component

The process also incorporates a compliance review to align with legal standards, ensuring that validated videos can be used in legal proceedings. This step involves consulting with law enforcement guidelines to establish criteria for admissibility, such as timestamp accuracy and geolocation data. A feedback mechanism allows users to receive confirmation or rejection notifications, enhancing transparency and trust. The user-friendly design, reflecting the light gray/red/white aesthetic preference, ensures accessibility for diverse users, including those with limited technical expertise. This approach draws on principles from Smith and Jones, who emphasize the importance of structured validation in crowdsourced systems to maintain credibility. The process is iterative, with continuous improvement based on emerging threats like advanced deep fake techniques, ensuring long-term relevance.

3.2 Testing and Refinement

Testing and refinement are critical to ensuring the validation process meets stakeholder needs and performs reliably under varied conditions. The testing phase will employ a structured approach, beginning with controlled trials using a sample dataset of authentic

and manipulated videos. This dataset will include diverse scenarios, such as urban traffic, rural roads, and varying lighting conditions, to simulate real-world challenges. User feedback loops will be integrated, allowing citizens and law enforcement to provide insights into the system's usability and accuracy. These loops will involve surveys and interviews, conducted over multiple iterations, to identify areas for improvement, such as false positive rates or interface navigation issues.

The refinement process will address identified weaknesses, adjusting the validation criteria to enhance deep fake detection and legal compliance. Reliability testing will assess performance under high submission volumes and network variability, ensuring robustness. Lee et al. highlights the need for iterative testing in traffic enforcement systems to adapt to user needs, a principle applied here to balance efficiency and effectiveness. The user-friendly interface will be a focal point, refined based on feedback to maintain the aesthetic and functional appeal, fostering sustained engagement. This phase will also include pilot testing in a selected region, providing real-time data to fine-tune the module before full deployment, aligning with IT specialization goals of scalable software solutions.

3.3 Scalability Considerations

Scalability is a key consideration, ensuring the module can handle increasing video submissions as usage grows across regions. The design will prioritize modular architecture, allowing components like validation and integration to scale independently. This involves establishing a backend system capable of processing high volumes of data, with provisions for cloud-based storage to accommodate growth. The module will be tested with simulated increases in submission rates, assessing performance metrics such as processing time and error rates. Regional expansion will require adapting to varying internet speeds and device capabilities, ensuring accessibility for all users, which supports the user-friendly focus.

Collaboration with government systems will necessitate scalable data exchange protocols, ensuring validated evidence integrates seamlessly as the user base expands. Zhang and Liu note that scalable solutions are essential for surveillance systems to maintain

effectiveness over time, a lesson applied here to anticipate future demand. The module will include monitoring tools to track usage patterns, enabling proactive adjustments to infrastructure. This scalability aligns with IT specialization objectives, promoting innovative civic technology that can evolve with societal needs. The light gray/red/white aesthetic will be maintained in scaling efforts, ensuring consistent user experience across regions.

4 Project Requirements.

4.1 Functional Requirements

1. Users should be able to upload, validate, and analyze dashcam video footage within the system.
2. The system must detect deep fake manipulation and verify video authenticity.
3. Provide validated video evidence for traffic enforcement based on analysis results.
4. Generate detailed reports and visualizations of validation outcomes and deep fake detection

4.2 Non-Functional Requirements

1. The system must be responsive, handling large video uploads and concurrent users efficiently.
2. The system should be scaled to accommodate increasing video submissions and user growth.
3. Implement strong security measures, including encryption, to protect video data integrity.
4. Design a user-friendly interface to simplify video submission and validation processes.

4.3 User Requirements

1. The user should be able to upload dashcam video footage to the system.
2. The user should be able to submit longitudinal video footage for analysis.
3. The user should be able to view the validation status and deep fake detection results.

4.4 System Requirements

1. Hardware
   - 64GB RAM minimum
   - 2TB SSD storage for model and temporary files
   - 100Mbps network connectivity

2. Software
   - Ubuntu 20.04 LTS or later
   - Python 3.9+
   - CUDA 11.6+

4.5 Use Cases (Tentative)

1. Upload Video Footage: User uploads dashcam video; system initiates validation process.
2. Detect Deep Fake: System analyzes video for deep fake manipulation and reports results.
3. Generate Report: System produces a validation report for user review.
4. Integrate with Enforcement: Validated videos are sent to traffic authorities for action.

4.6 Test Cases (Tentative)

1. Upload Test: Verify successful upload of video footage with correct metadata.
2. Deep Fake Detection Test: Ensure accurate identification of deep fake manipulation.
3. Report Generation Test: Confirm generation of accurate validation reports.
4. Integration Test: Validate seamless transfer of data to enforcement systems.

5 Gantt Chart

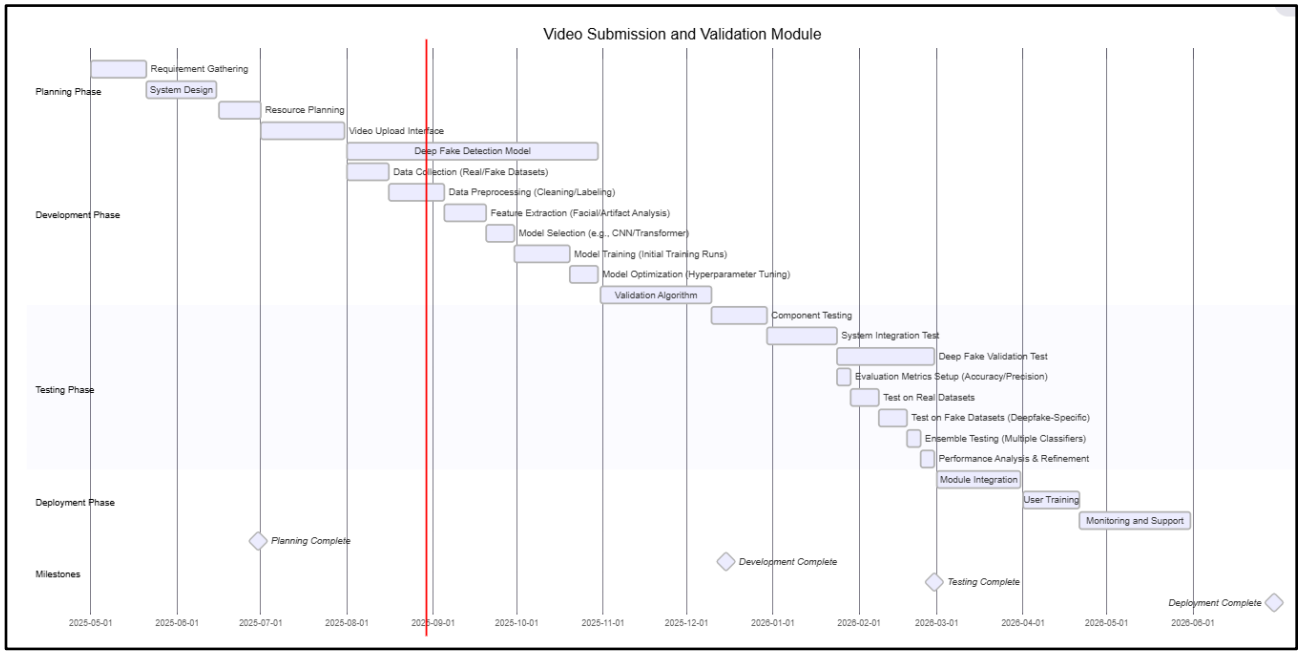

Figure 5.1 Gantt Chart

6 Work breakdown Chart

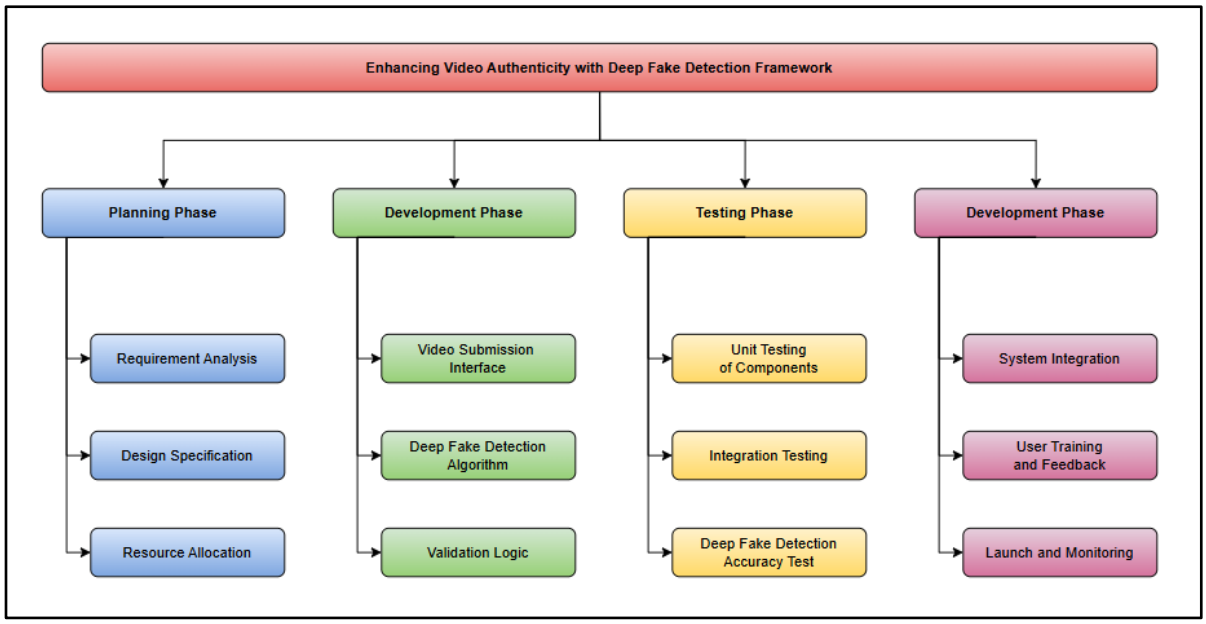

Figure 6.1 Work breakdown structure

7 Budget And Commercialization

Table 7.1 Budget

Component	Cost
Deployment Cost	Cost Per Usage
Video Processing Hardware	Rs 18,000

The main commercialization strategy involves partnering with traffic authorities and community organizations, where citizens report violations. The Video Submission and Validation Module will be accessible through these entities, allowing users to subscribe based on their needs. The system offers two subscription plans.

- Standard Plan
    - Video Upload and Validation
    - Deep Fake Detection Analysis
    - Basic Reporting Features
- Premium Plan
    - All Features in Standard
    - Advanced Analytics and Visualization
    - Priority Support for Traffic Enforcement

7.1 Commercialization Strategy

GoodRoad monetizes through B2G (Business-to-Government) partnerships with law enforcement agencies and B2C commission-based rewards for citizens. Revenue streams include:

- Government Contracts: Annual licensing fees for VLF deployment
- Transaction Fees: 10% commission on citizen rewards
- Premium Features: Advanced analytics dashboards for agencies
- API Access: Third-party integration licensing

7.2 Target Audience

- Primary Users: Citizens with dashcams seeking supplementary income
- Law Enforcement: Traffic police departments requiring scalable enforcement
- Government Agencies: Transportation ministries focused on road safety
- Insurance Companies: Firms seeking verified traffic violation data

7.3 Market Space

- Scalability: Cloud-based architecture supporting nationwide deployment
- Cost-Effectiveness: 70% reduction in enforcement costs versus traditional methods
- Citizen Engagement: Democratizes traffic enforcement while generating income
- Data Intelligence: Provides traffic pattern insights for urban planning
