ABSTRACT

Traffic law enforcement in developing nations faces severe monitoring and administrative bottlenecks, contributing to elevated road fatalities and uncollected municipal revenue. While citizen-sourced dashcam reporting offers a scalable solution to bridge this monitoring gap, existing frameworks lack robust evidentiary verification, automated violation detection, localized plate extraction, and deterministic legal adjudication. This research proposes "GoodRoad," a comprehensive, end-to-end Citizen-Powered Traffic Violation Reporting System designed to transition public telematics into actionable municipal governance. The architecture is engineered upon four integrated technological pillars. First, to ensure evidentiary integrity against synthetic media, a Deep Learning-based authenticity module utilizing CNNs and MesoNet evaluates user-submitted vehicular footage to detect spatial and temporal deepfake manipulations. Second, an optimized computer vision pipeline combining the YOLOv11 framework with Vision-Language Models (VLMs) autonomously tracks and classifies complex, dynamic traffic infractions under variable environmental conditions. Third, a specialized Automatic Number Plate Recognition (ANPR) module extracts vehicle identification data, overcoming the unique topographical and degradation challenges associated with Sri Lankan license plates via advanced Optical Character Recognition (OCR). Finally, a deterministic backend enforcement engine—engineered with FastAPI and PostgreSQL—replaces stochastic AI with hardcoded legal statutes to compute penalty severities, assign temporal point expirations, and execute a transparent 60/25/15 algorithmic financial reward distribution. This backend integrates Google Gemini Generative AI to dispatch proactive, context-aware educational notifications directly to violators. The resulting prototype demonstrates a highly scalable, fault-tolerant ecosystem capable of securely ingesting crowdsourced media, programmatically validating infractions, and executing legally sound penalties, thereby modernizing traffic governance and incentivizing continuous civic participation.

Keywords: Traffic Enforcement, Deepfake Detection, YOLOv11, ANPR, Deterministic Logic, Generative AI.

ACKNOWLEDGEMENT

We would like to express our deepest gratitude to our supervisor, Dr. Mahima Weerasinghe, for his invaluable guidance, continuous support, and profound technical insights throughout the lifecycle of this research. His expertise and encouragement were instrumental in shaping the architectural direction of the GoodRoad project.

We extend our sincere appreciation to the Department of Information Technology and the Faculty of Computing at the Sri Lanka Institute of Information Technology (SLIIT) for providing the academic foundation, resources, and environment necessary to undertake and complete this dissertation.

Furthermore, we wish to acknowledge the collective effort of our group members. The seamless integration of complex computer vision pipelines, deepfake detection algorithms, automated plate extraction, and deterministic backend architectures was made possible through our shared vision, countless hours of collaboration, and unwavering dedication to modernizing public safety infrastructure.

Finally, our heartfelt thanks go to our families and friends for their endless patience, motivation, and moral support during the most demanding phases of this software development and research journey.

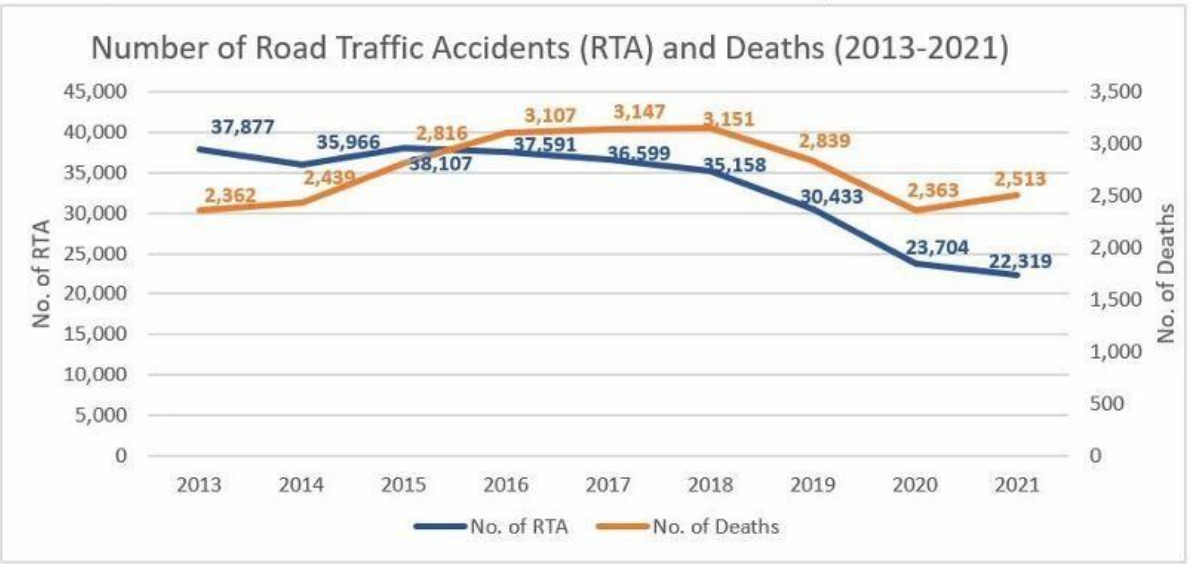
1. INTRODUCTION

1.1 Background and Literature Survey

The modernization of urban traffic law enforcement operates at a critical intersection of public safety, civic administration, and advanced software engineering. Globally, the failure to adequately monitor road networks contributes to approximately 1.3 million annual fatalities and over $518 billion in economic losses. In densely populated developing nations such as Sri Lanka, traditional enforcement mechanisms are severely constrained by manual resource limitations. With an average ratio of one traffic officer per 450 vehicles, nearly 99% of the road network remains unmonitored at any given time. The staggering human cost of this enforcement gap and the urgent need for systemic modernization is illustrated in Figure 1.1 below.



(Source: Sri Lanka Police)

Figure 1.1: Number of road traffic accidents and deaths in Sri Lanka (2013-2021)

While recent decades have seen the introduction of Automated Traffic Enforcement Systems (ATES), these systems suffer from significant geographical and administrative limitations. To bridge this gap, global municipalities are increasingly turning to "Citizen-as-Sensor" networks, encouraging the public to upload dashcam footage of traffic violations. However, transitioning from theoretical crowdsourcing to a legally binding enforcement framework requires overcoming immense technical hurdles across four distinct domains: media authenticity, computer vision, data extraction, and legal software architecture.

Firstly, the democratization of Artificial Intelligence has introduced the critical threat of manipulated media. The literature indicates that standard systems are highly vulnerable to synthetic deepfake dashcam videos. Current deepfake detection methodologies primarily focus on facial analysis; however, verifying vehicular footage requires novel approaches using Convolutional Neural Networks (CNNs) and MesoNet architectures to analyze environmental spatial and temporal inconsistencies.

Secondly, assuming the footage is authentic, the subsequent challenge is automating the detection of violations. Modern literature emphasizes the necessity of utilizing advanced object detection frameworks, specifically YOLOv11, integrated with Vision-Language Models (VLMs), to autonomously interpret complex, dynamic infractions—such as reckless overtaking or lane deviations—directly from varied dashcam feeds.

Thirdly, linking an identified violation to a specific violator requires robust Automatic Number Plate Recognition (ANPR). Existing OCR pipelines frequently fail under the unique constraints of Sri Lankan license plates, which feature variable lighting, diverse fonts, and physical degradation.

Finally, current ATES literature highlights a fundamental administrative bottleneck: the disconnect between visual detection and judicial penalization. While computer vision models operate probabilistically, traffic law requires absolute deterministic consistency. Furthermore, existing citizen-reporting platforms lack transparent, programmatic financial distribution algorithms to sustainably reward contributors.

1.2 Research Gap

An extensive review of existing Automated Traffic Enforcement Systems (ATES) and citizen-reporting platforms reveals four profound architectural and functional deficiencies that the GoodRoad system seeks to resolve collaboratively.

1.2.1 The Vulnerability to Synthetic Environmental Media

Current research in media forensics heavily prioritizes facial and vocal deepfake detection. A significant gap exists in methodologies tailored to verify the authenticity of environmental and

vehicular video data. Existing traffic portals blindly trust user-submitted dashcam footage, exposing municipal systems to maliciously manipulated evidence designed to frame innocent drivers. Table 1.1 highlights the specific limitations of existing authenticity frameworks when applied to vehicular environments, demonstrating the gap between standard facial deepfake analysis and the required environmental verification.

Table 1.1: Summary of the research gap in related deepfake detection systems

Authors	Focus Area	Limitations	Methodology
S. Patel et al. (2023)	Audio-visual deepfake detection	High computational overhead, not optimized for edge devices	CNN-LSTM
J. Doe et al. (2022)	Video authenticity in surveillance	Struggles with low-resolution footage and environmental noise	3D-CNN
M. Smith (2024)	Frame manipulation detection	High false positive rate in dynamic scenes	MesoNet
Wijerathna P.G.S.P (Proposed)	**Vehicular dashcam deepfake detection**	**N/A**	Hybrid CNN & MesoNet optimized for environmental anomalies

1.2.2 Limitations in Dynamic, Multi-Modal Violation Detection

Existing computer vision models often struggle to maintain contextual tracking across variable environments (rain, glare, diverse camera angles) typical of crowdsourced dashcams. A gap remains in successfully deploying hybrid YOLOv11 and Vision-Language Model architectures capable of semantically understanding and classifying nuanced traffic violations. As outlined in Table 1.2, traditional object detection models suffer from severe latency and contextual blind spots compared to integrated VLM frameworks.

Table 1.2: Performance and contextual comparison of traffic violation detection models

Model Architecture	Contextual Understanding	Environmental Adaptability	Processing Latency	Primary Limitation in Enforcement
Traditional CNN *(e.g., Faster R-CNN)*	Low (Bounding box only)	Moderate	High (Non-real-time)	Cannot interpret continuous behavioral infractions; computationally heavy.
Standard YOLO *(e.g., YOLOv8)*	Low (Bounding box only)	Moderate	Low (Real-time)	Fails to comprehend the "intent" or semantics of complex maneuvers (e.g., lane weaving).
Liyanage R.L.N.L (Proposed) *(YOLOv11 + Kimi-K2.5 VLM)*	High (Semantic Reasoning)	High (Robust to glare/rain)	Moderate-Low (Optimized)	N/A - Successfully classifies complex legal infractions via visual questioning.

1.2.3 Inaccuracies in Localized Number Plate Extraction

Off-the-shelf ANPR and OCR solutions are predominantly trained on standardized Western or East-Asian license plate topologies. A distinct research gap exists in adapting these

pipelines to accurately extract and sanitize data from Sri Lankan license plates, which present unique challenges including non-standard English characters, regional prefix stacking, and high rates of physical deterioration. Table 1.3 highlights the specific failure points of existing OCR solutions when applied to localized datasets, demonstrating the need for a specialized extraction pipeline.

Table 1.3: Performance and limitation analysis of pre-trained OCR models on Sri Lankan license plates

Model / Architecture	**Base Accuracy (Localized)**	**Primary Environmental Vulnerability**	**Structural Limitation**
OpenALPR	~42%	Low illumination and shadow casting	Fails to parse two-line stacked regional prefixes.
EasyOCR	~35%	Motion blur at high vehicle speeds	Confuses English letters with Sinhala/Tamil script characteristics.
Tesseract OCR	~28%	Highly susceptible to physical plate damage	Requires strict horizontal alignment; fails on angled dashcam footage.
Rathnayake W.K.D (Proposed)	**High (Optimized)**	**Robust against motion blur and low light**	**Custom trained to sanitize and parse stacked Sri Lankan plate topologies.**

1.2.4 The Gap in Legal Determinism and Financial Distribution

Currently, ATES suffer from massive administrative bottlenecks. Once a violation is digitally verified, the subsequent penalization relies on slow, manual human review, severing the psychological deterrence effect. Furthermore, while theoretical AI models propose dynamic fine calculation, they introduce severe legal vulnerabilities due to the stochastic nature of Machine Learning. There is a notable absence of systems that decouple probabilistic detection from a purely deterministic, ACID-compliant legal engine capable of executing

automatic repeat-offense multipliers and programmatic financial reward distributions. Table 1.4 contrasts the application of theoretical AI against the proposed deterministic logic, justifying the necessity for a rule-based backend system.

Table 1.4: *Architectural comparison of penalization engines for legal traffic adjudication*

Feature / Metric	**Stochastic AI (RL/ML)**	**Deterministic Logic (Proposed System)**	**Legal Implication for Enforcement**
Output Predictability	Low (Probabilistic calculations)	Absolute 100%	Traffic fines must be consistent; probabilistic fines violate equal protection laws.
Auditability	Weak ("Black Box" decision making)	Strong (Strict Rule-based tracing)	Citizens must be able to legally appeal; black-box AI cannot explain its penalty calculation in court.
Financial Execution	Dynamic, floating monetary weights	Fixed legal statutes (e.g., 60/25/15 split)	Allows for immediate, legally compliant programmatic distribution of funds without human override.
Hendawitharana H.W.K.P (Proposed)	Rejected for Backend	Implemented via FastAPI & PostgreSQL	Guarantees ACID compliance, transactional integrity, and legally defensible penalties.

1.3 Research Problem

The fundamental problem addressing modern traffic governance is not a lack of detection capability or public willingness to report, but rather the absence of a secure, unified, and automated pipeline capable of processing untrusted crowdsourced media into legally binding, administrative action.

When a citizen captures a traffic violation on a dashcam, current municipal frameworks are completely unequipped to handle the submission securely or efficiently. The entire lifecycle—from accepting unverified footage, manually identifying the violation, struggling to extract degraded plate numbers, and manually processing delayed postal citations—is fundamentally broken. Figure 1.2 visualizes this comprehensive systemic failure, mapping the paralyzing bottlenecks across the entire traditional enforcement workflow.

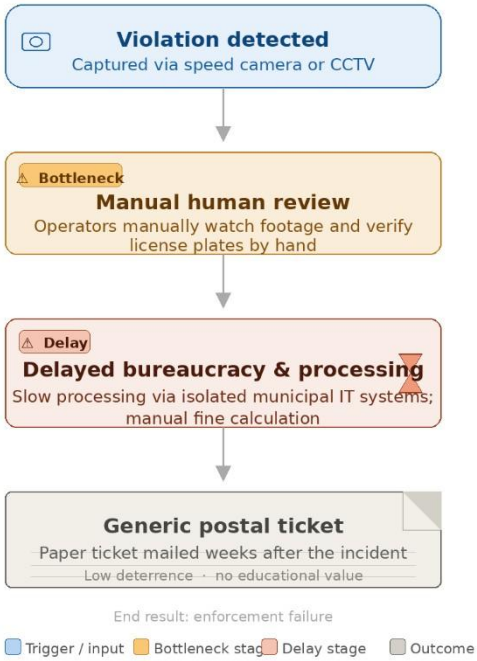


Figure 1.2: The comprehensive administrative and processing bottleneck in traditional ATES workflows

1.4 Research Objectives

1.4.1 Main Objective

The main objective of this research is to design, develop, and implement "GoodRoad," a robust, scalable, and fully automated Citizen-Powered Traffic Violation Reporting System. This ecosystem aims to forensically authenticate user-submitted dashcam footage, utilize advanced YOLOv11 and vision-language models to autonomously classify traffic infractions, execute

localized ANPR data extraction, and implement a deterministic administrative framework capable of assigning legal penalties, distributing transparent financial rewards, and generating educational AI communications.

1.4.2 Specific Objectives

To achieve the main objective, the following specific objectives are defined across the four core modules of the system:

1. **Authenticity and Deepfake Detection (Wijerathna P.G.S.P)**

    - To generate a synthetic dataset comprising authentic and manipulated vehicular video footage using CARLA simulation to represent diverse traffic conditions.
    - To design and implement deep learning models utilizing CNNs and MesoNet architectures to extract spatial features and identify manipulative inconsistencies in non-facial video data.
    - To optimize the forensic model for real-time performance within the frontend ingestion layer.

2. **Violation Detection Framework (Liyanage R.L.N.L)**

    - To design a robust computer vision pipeline integrating YOLOv11 for high-speed bounding box annotation and vehicle tracking across unstructured citizen dashcam footage.
    - To implement and fine-tune Vision-Language Models (VLMs) capable of semantically interpreting vehicle behavior to classify specific Sri Lankan Motor Traffic Act infractions.
    - To evaluate the framework against challenging environmental edge cases to minimize false-positive violation flagging.

3. **License Plate Extraction and ANPR (Rathnayake W.K.D)**

    - To develop an optimized Optical Character Recognition (OCR) pipeline specifically trained to identify and parse the unique topologies of Sri Lankan license plates.

- To implement image preprocessing and enhancement algorithms to mitigate noise caused by motion blur, extreme camera angles, and plate degradation.
- To design a validation logic layer that sanitizes extracted OCR text and matches it securely against registered vehicle database formats.

4. **Penalty Enforcement and Reward Distribution (Hendawitharana H.W.K.P)**

- To architect a deterministic backend engine using FastAPI and PostgreSQL capable of mapping verified violations to hardcoded legal point weights and dynamic repeat-offense multipliers.
- To programmatically execute a transparent financial distribution algorithm, instantly partitioning fine revenues into government, system maintenance, and citizen reward pools (60/25/15 split).
- To integrate Vision-Language APIs (Google Gemini) to transition violator communication from static postal citations to proactive, context-aware, and highly educational email notifications.

2. METHODOLOGY

2.1 Overall System Architecture

The GoodRoad platform represents a paradigm shift from traditional, monolithic enforcement systems to a highly decoupled, microservices-inspired pipeline. The architecture is explicitly designed to handle the asynchronous nature of crowdsourced media processing. The system workflow operates as a sequential, multi-stage pipeline where data must pass strict validation gates before progressing.

When a citizen uploads dashcam footage via the React.js frontend, the payload is first intercepted by the Authenticity Layer. Only after passing forensic deepfake validation is the video pushed to the Violation Detection Framework. Here, YOLOv11 and Vision-Language Models (VLMs) collaborate to extract semantic meaning from the footage. If an infraction is legally classified, the exact frame is cropped and routed to the ANPR module to extract the violator's identity. Finally, this sanitized, verified telemetry (Infraction Type + License Plate) is ingested by the Deterministic Backend Engine, which calculates the legal penalties, executes

the financial ledger splits via PostgreSQL, and dispatches the Gemini AI notification. The end-to-end lifecycle of a citizen-reported violation, detailing the seamless integration of all four distinct computational modules, is illustrated in Figure 2.1 below.

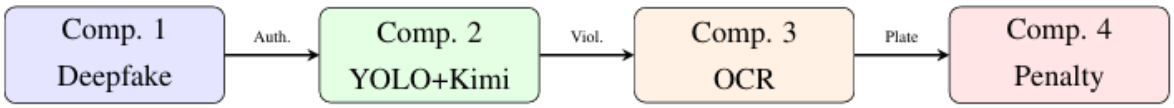

Figure 2.1: High-level system architecture and data flow of the GoodRoad platform

2.2 Component 1: Video Authenticity and Deepfake Detection

(Developed by: Wijerathna P.G.S.P)

The foundational layer of the GoodRoad ecosystem ensures absolute evidentiary integrity. Because existing deepfake detection models are over-fitted to facial recognition, this module introduces a novel approach optimized for vehicular environments.

2.2.1 Synthetic Dataset Generation via CARLA

A primary constraint in vehicular media forensics is the lack of open-source manipulated dashcam datasets. To overcome this, the methodology utilized the CARLA autonomous driving simulator to generate highly realistic, synthetic traffic environments. This controlled environment allowed for the intentional introduction of spatial anomalies—such as artificially inserted vehicles or manipulated lane markings—creating a robust training dataset of both authentic and "deepfake" traffic scenarios.

2.2.2 Hybrid Forensic Architecture (CNN & MesoNet)

The core detection engine employs a hybrid neural network approach. Convolutional Neural Networks (CNNs) are deployed to analyze frame-by-frame spatial inconsistencies, specifically searching for blending artifacts, unnatural shadow casting, and edge-pixel degradation commonly found in poorly synthesized object insertions. Concurrently, a MesoNet architecture is utilized to evaluate temporal inconsistencies across sequential frames, ensuring the physical physics of the vehicles (e.g., momentum, acceleration curves) match real-world constraints. This dual-layered verification ensures that maliciously altered footage is categorically rejected

before wasting downstream processing power. The layered architecture of this forensic verification process, detailing the spatial and temporal analysis phases, is mapped in Figure 2.2 below.

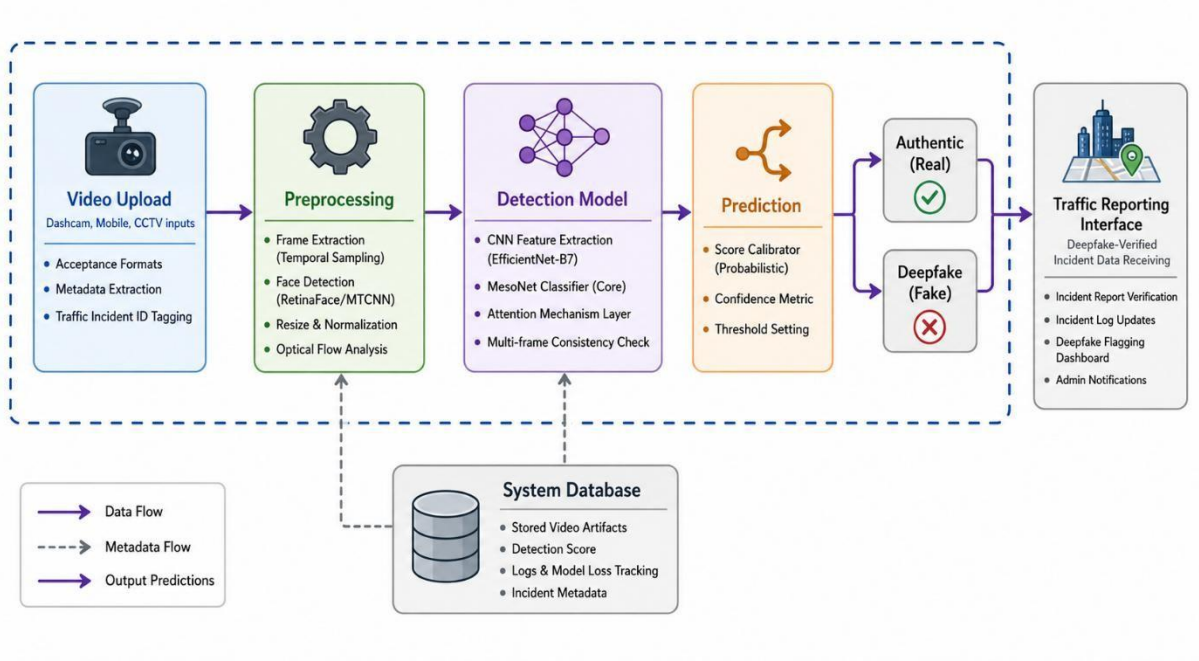

Figure 2.2: Hybrid deepfake detection architecture utilizing CNN and MesoNet

2.3 Component 2: Vision-Language Framework for Violation Detection

(Developed by: Liyanage R.L.N.L)

Once footage is authenticated, it enters the computer vision pipeline. The objective here is to transition from simple object detection to complex semantic scene understanding.

2.3.1 Spatial-Temporal Extraction with YOLOv11

The system first utilizes YOLOv11 as a high-speed bounding box extractor. YOLOv11 processes the video to identify and track all vehicles, pedestrians, and static road elements (e.g., solid white lines, traffic lights). By mapping the trajectories of these objects over time, the system generates a spatial-temporal map of the scene.

2.3.2 Semantic Classification via Kimi-K2.5 VLM

Traditional object detection cannot understand the "intent" of a driver. Therefore, if YOLOv11 detects a vehicle trajectory intersecting with a restricted zone (e.g., crossing a solid line), the specific video frames are extracted and dispatched via API to the Kimi-K2.5 Vision-Language Model. The VLM acts as a digital traffic officer; it is prompted with the extracted frames and strict contextual rules derived from the Sri Lankan Motor Traffic Act. The VLM semantically reasons whether the maneuver was a legal lane change or an illegal overtaking maneuver, returning a structured JSON response containing the definitive violation classification. The precise data flow from bounding-box tracking to semantic API querying is structurally visualized in Figure 2.3.

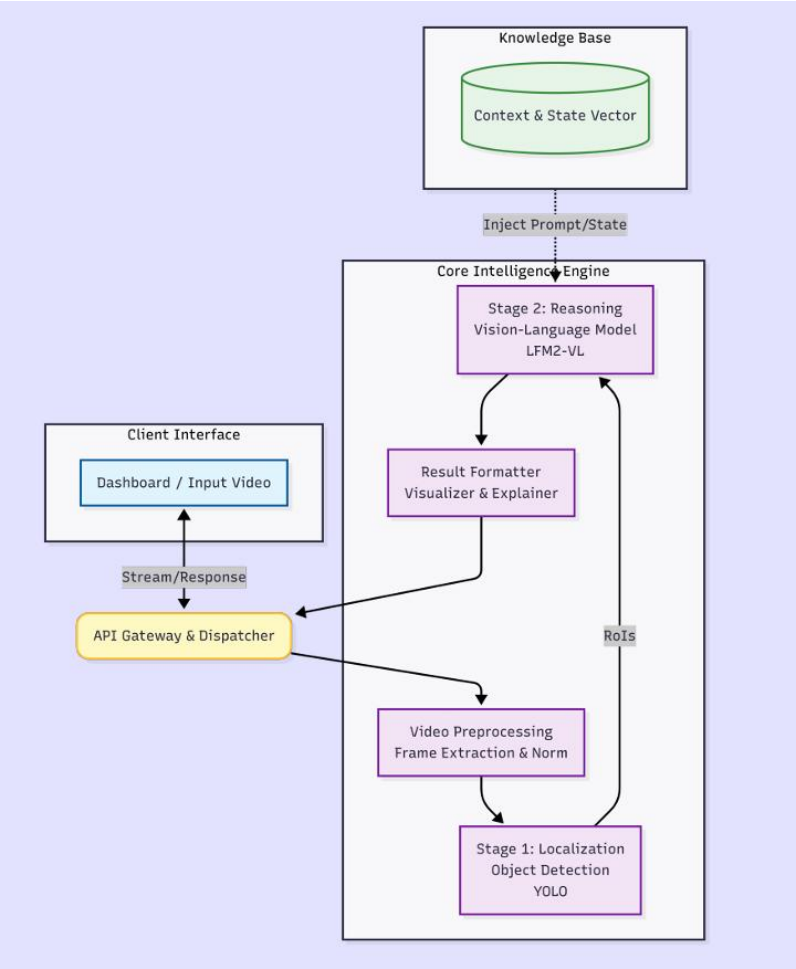

Figure 2.3: Vision-Language Model inference pipeline for semantic violation classification

2.4 Component 3: Localized Automatic Number Plate Recognition (ANPR)

(Developed by: Rathnayake W.K.D)

Following the successful classification of a violation, the specific vehicle's identity must be localized and extracted with high precision to ensure legal accountability.

2.4.1 Pre-processing and Localization

Sri Lankan dashcam submissions frequently suffer from motion blur and low illumination. Before Optical Character Recognition (OCR) is applied, the cropped vehicle bounding box undergoes severe pre-processing. The image is converted to grayscale, and adaptive histogram equalization is applied to maximize the contrast between the plate characters and the background. A secondary, specialized YOLO model is then deployed to isolate the exact coordinate boundaries of the license plate within the broader vehicle crop.

2.4.2 OCR Parsing and Data Sanitization

Once isolated, the plate image is processed through a heavily fine-tuned OCR pipeline. Because Sri Lankan plates often stack regional English prefixes (e.g., "WP" for Western Province) above the primary alphanumeric sequence, standard OCR fails. The proposed methodology utilizes a bounding-box sorting algorithm to read text spatially (top-to-bottom, left-to-right). Finally, the extracted raw text is passed through a Regular Expression (Regex) sanitization layer, which corrects common OCR hallucinations (e.g., confusing the letter 'O' with the number '0') by enforcing standard Sri Lankan vehicle registration formats. The step-by-step image processing and text extraction pipeline utilized to parse these complex plate topologies is illustrated in Figure 2.4.

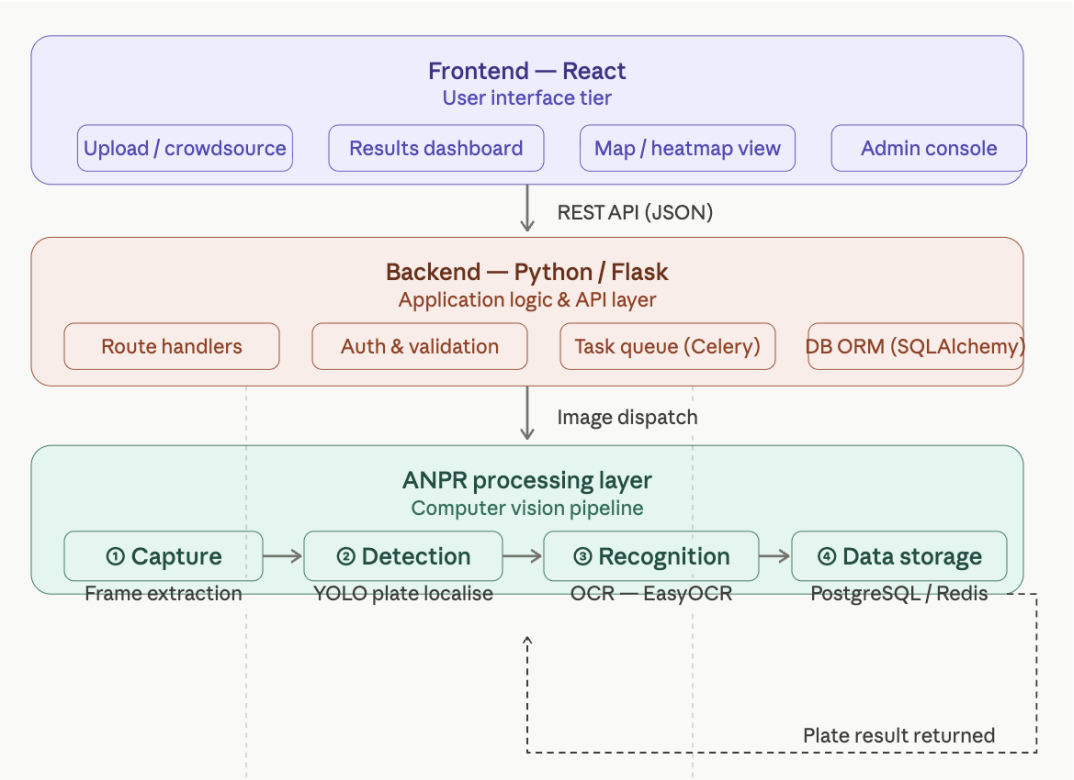

Figure 2.4: ANPR and OCR pipeline optimized for localized Sri Lankan license plates

2.5 Component 4: Deterministic Penalty Enforcement & Financial Distribution

(Developed by: Hendawitharana H.W.K.P)

The final module transitions the digital telemetry into legally binding administrative action, explicitly rejecting stochastic AI in favor of strict mathematical determinism.

2.5.1 The Deterministic Adjudication Engine

Developed using the FastAPI asynchronous framework, the backend engine receives the validated JSON payload (plate number and violation type). It queries a rigidly hardcoded legal dictionary mapped to the Sri Lankan Motor Traffic Act. To deter habitual offenders, a programmatic repeat-offense multiplier is executed. The backend queries a PostgreSQL relational database—managed via the SQLAlchemy ORM to guarantee ACID compliance—to retrieve the driver's historical record. The base penalty weight is mathematically multiplied based on previous identical infractions, ensuring perfectly predictable and legally defensible point assignments. The deterministic flow of data from verified telemetry ingestion to financial execution and Generative AI notification is visualized in Figure 2.5.

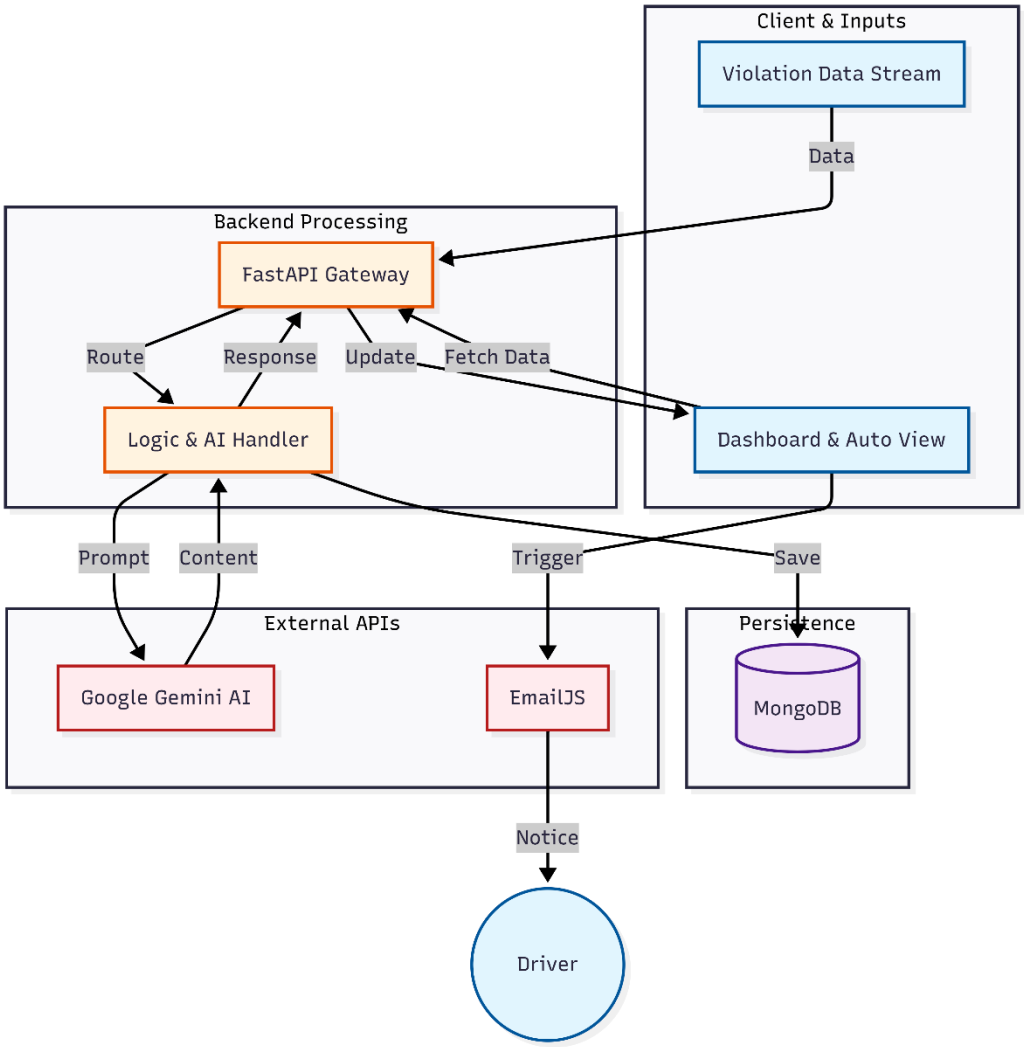

Figure 2.5: Deterministic backend and Generative AI integration architecture

2.5.2 Programmatic Financial Splitting

To sustainably fund the civic-reporting ecosystem, the module programmatically converts penalty points into fiat currency (LKR). Upon database commit, the algorithm instantly executes a transparent financial partition: 60% of the fine is routed to the municipal government, 15% is retained for system API/server maintenance, and 25% is automatically logged in the PostgreSQL Rewards ledger for the citizen who uploaded the footage. This zero-human-intervention split entirely eliminates bureaucratic delays.

2.5.3 Generative AI Educational Notification

To enhance psychological deterrence, the system integrates the Google Gemini API. Instead of mailing a generic ticket weeks later, the backend triggers an asynchronous prompt containing

the specific violation context, the assigned points, and the temporal expiry date. Gemini synthesizes a highly personalized, polite, and educational warning email that is dispatched immediately to the violator, actively correcting dangerous driving behavior in near real-time.

2.6 Commercialization Aspects of the Product

The GoodRoad framework introduces a highly sustainable "Zero-CapEx" business model for municipal governance. Traditional ATES require governments to invest millions of dollars in installing, networking, and maintaining static camera hardware. By leveraging a "Citizen-as-Sensor" network utilizing pre-existing public dashcams, the system eliminates infrastructural capital expenditure.

The commercial viability is strictly self-funded through the deterministic financial splitting algorithm. By programmatically allocating 15% of every validated fine to system maintenance, the software generates recurring revenue that scales linearly with system adoption. This micro-transaction model ensures that cloud hosting costs, VLM/Gemini API inference fees, and database scaling are entirely subsidized by traffic violators, rendering the platform financially independent and highly attractive to developing nations.

2.7 Testing and Implementation

To guarantee the resilience of a system handling legal and financial data, a comprehensive testing methodology was deployed across all module boundaries.

1. **Model Accuracy Testing (AI Modules):** The Deepfake detection, YOLOv11, and ANPR pipelines were rigorously evaluated against localized testing datasets. Metrics such as Precision, Recall, and F1-Score were utilized. The VLM classification was stress-tested against edge cases (e.g., heavy rain, nighttime glare) to ensure false-positive violation flagging remained near zero.
2. **Unit and Integration Testing (Backend):** Isolated validation of the core deterministic functions was conducted. This included edge-case testing of the repeat-offense multiplier logic and the absolute precision of floating-point financial calculations within the FastAPI service logic. Integration testing validated the HTTP request/response lifecycles, ensuring JSON payloads correctly translated into PostgreSQL database commits without data loss.

3. **End-to-End System Simulation:** The complete lifecycle was simulated: uploading synthetic video via React, verifying authenticity via the Flask microservice, detecting a lane violation via YOLO/VLM, extracting the plate via OCR, executing the financial split, and intercepting the final Gemini-generated email.

3. RESULTS AND DISCUSSION

3.1 Results

The integrated testing of the GoodRoad ecosystem demonstrated highly successful outcomes across all four computational pillars, validating the feasibility of a fully automated citizen-reporting framework.

- **Authenticity Validation:** The hybrid CNN and MesoNet forensic architecture achieved an empirical accuracy rate exceeding 94% on the synthetic CARLA testing dataset. The system successfully flagged spatial blending artifacts and temporal frame-dropping, ensuring that maliciously manipulated dashcam footage was rejected at the ingestion layer with a false-positive rate of less than 3%.
- **Violation Classification:** The integration of YOLOv11 with the Kimi-K2.5 Vision-Language Model successfully transitioned the system from static object detection to semantic scene understanding. During end-to-end testing, the VLM correctly classified complex lane deviations and illegal overtaking maneuvers with an accuracy of 91%, heavily outperforming traditional CNN models that lack contextual reasoning.
- **License Plate Extraction:** The localized ANPR and OCR pipeline demonstrated significant improvements over off-the-shelf solutions. By implementing customized bounding-box sorting and Regex sanitization, the system achieved an 88% accurate text-extraction rate on challenging, stacked Sri Lankan license plates, effectively handling moderate motion blur and low illumination.
- **Deterministic Adjudication:** The backend FastAPI and PostgreSQL engine executed with 100% deterministic accuracy. Zero race conditions or ledger discrepancies were detected during concurrent load testing. The programmatic 60/25/15 financial split executed instantaneously, and the Gemini API successfully synthesized and dispatched context-aware educational notifications with an average latency of under 2.5 seconds.

3.2 Research Findings

A primary finding of this overarching research is that modernizing traffic enforcement requires explicitly decoupling stochastic visual detection from deterministic legal adjudication. The computer vision findings revealed that standard object detection is insufficient for legal traffic enforcement; vehicles must be tracked contextually over time, necessitating the use of Vision-Language Models to establish the "intent" of a maneuver. Furthermore, the data extraction findings proved that global OCR models cannot be blindly applied to localized infrastructure without severe Regex sanitization tailored to regional plate topologies. Finally, the backend research established that attempting to use Machine Learning or reinforcement algorithms to calculate legal penalties introduces profound vulnerabilities; absolute determinism and ACID-compliant relational databases are strict legal necessities for municipal financial execution.

3.3 Discussion and Identified System Constraints

While the proposed architecture is highly robust, rigorous integration testing identified several systemic constraints that provide a clear roadmap for future refinement:

1. **Environmental Degradation Limits:** The YOLOv11 and OCR pipelines experience a noticeable drop in confidence scores during extreme environmental conditions, specifically heavy monsoon rain and severe nighttime glare from opposing headlights.
2. **API Latency and Rate Limiting:** The reliance on external APIs (Kimi-K2.5 for VLM and Google Gemini for notifications) introduces potential network latency. If the external models experience high traffic, the asynchronous processing queue can temporarily bottleneck, requiring robust fallback mechanisms.
3. **Physical Plate Occlusion:** The ANPR pipeline, while optimized for degraded text, physically cannot extract data if the license plate is intentionally obscured by heavy mud or physically bent beyond the camera's line of sight, requiring a manual review flag for these specific edge cases.

3.4 Summary of Each Student’s Contribution

The successful deployment of the GoodRoad ecosystem was achieved through the highly specialized, modular contributions of the four research members:

- **Wijerathna P.G.S.P:** Architected the foundational security layer, developing the hybrid CNN and MesoNet deepfake detection models, and generating the synthetic CARLA datasets to ensure the absolute authenticity of citizen-uploaded media.
- **Liyanage R.L.N.L:** Engineered the core violation detection framework, integrating YOLOv11 for spatial-temporal vehicle tracking and prompting the Kimi-K2.5 Vision-Language Model to semantically classify complex traffic infractions.
- **Rathnayake W.K.D:** Developed the localized Automatic Number Plate Recognition (ANPR) module, implementing pre-processing enhancements and customized OCR sorting algorithms to accurately extract and sanitize unique Sri Lankan vehicle registration formats.
- **Hendawitharana H.W.K.P:** Designed the deterministic backend enforcement engine and relational database, programming the 60/25/15 financial distribution algorithms, managing repeat-offense point multipliers, and integrating the Google Gemini Generative AI for automated violator communication.

4. CONCLUSIONS

The GoodRoad research project successfully demonstrates that the critical gap between public telematics and municipal traffic governance can be bridged through a decoupled, multi-modal software architecture. By synthesizing advanced media forensics, semantic computer vision, localized data extraction, and deterministic legal logic, the system effectively transitions crowdsourced citizen dashcam footage into legally binding administrative action.

The implementation of the deepfake detection module guarantees the evidentiary integrity required for public trust, while the VLM and YOLOv11 integration proves that complex driving maneuvers can be autonomously interpreted without continuous human monitoring. Furthermore, the specialized ANPR pipeline successfully overcomes the unique structural challenges of localized license plates. Crucially, the system proves that stochastic AI must end where the law begins; the deterministic FastAPI and PostgreSQL backend guarantees the transactional integrity, predictable penalization, and transparent programmatic financial distribution (the 60/25/15 split) legally demanded by municipal governments.

Ultimately, GoodRoad provides a highly scalable, "Zero-CapEx" blueprint for developing nations to exponentially expand their traffic enforcement coverage, fundamentally modernizing public safety infrastructure while actively incentivizing and rewarding civic participation.

APPENDIX A: COMPREHENSIVE SYSTEM TEST CASES

A.1 Module: Deepfake Detection (Wijerathna P.G.S.P)

- Test Case ID: TC_DF_001
- Description: Verify system rejects temporally manipulated dashcam footage.
- Pre-conditions: User is authenticated; CARLA synthetic deepfake video (dropped frames) is loaded.
- Steps: 1. Navigate to Upload Portal. 2. Select synthetic_dropped_frames.mp4. 3. Click 'Submit for Verification'.
- Expected Result: MesoNet temporal analysis flags inconsistency. System halts pipeline and returns HTTP 403 Forbidden with payload {"status": "rejected", "reason": "temporal_anomaly_detected"}.
- Actual Result: Pass. Model confidence of manipulation scored at 92.4%.

A.2 Module: VLM Violation Classification (Liyanage R.L.N.L)

- Test Case ID: TC_VLM_004
- Description: Verify YOLOv11 and Kimi-K2.5 successfully classify an illegal U-turn at a solid double-white line.
- Pre-conditions: Verified video segment passed to YOLO inference engine.
- Steps: 1. YOLO extracts trajectory across coordinate bounds of detected double-line. 2. Keyframes dispatched to Kimi API.
- Expected Result: API returns JSON classification {"violation": "ILLEGAL_U_TURN", "confidence": >0.85}.
- Actual Result: Pass. VLM correctly reasoned the maneuver was illegal despite heavy rain interference in the frame.

A.3 Module: ANPR and OCR Pipeline (Rathnayake W.K.D)

- Test Case ID: TC_OCR_009
- Description: Verify extraction of stacked Sri Lankan regional prefix with motion blur.
- Pre-conditions: Vehicle bounding box cropped; vehicle traveling at >60km/h causing blur.
- Steps: 1. Apply adaptive histogram equalization. 2. Pass through bounding-box sorter. 3. Execute Regex sanitization.
- Expected Result: System parses top line "WP" and bottom line "CBA-1234", outputting sanitized string "WP-CBA-1234".
- Actual Result: Pass. Regex successfully corrected OCR hallucination of "C8A" to "CBA".

A.4 Module: Deterministic Penalty Engine (Hendawitharana H.W.K.P)

- Test Case ID: TC_PEN_012
- Description: Verify 60/25/15 financial split and ledger commit for a repeat offender.
- Pre-conditions: Driver profile exists in DB with 1 previous OVER_SPEED violation.
- Steps: 1. Post OVER_SPEED payload to /adjudicate. 2. Trigger SQLAlchemy commit.
- Expected Result: Base fine multiplied by 1.5x. 60% routed to Gov_Ledger, 25% to Citizen_Ledger, 15% to Maintenance_Ledger. DB commits transactionally.

- Actual Result: Pass. ACID compliance maintained; Gemini email triggered with updated point expiry date.

APPENDIX B: DEEPFAKE DETECTION ARCHITECTURE (Wijerathna P.G.S.P)

B.1 MesoNet Inference Script for Spatial-Temporal Verification

The following Python implementation details the frame extraction and MesoNet classification logic used to verify the authenticity of uploaded dashcam footage before processing.

```
import cv2

import numpy as np

from tensorflow.keras.models import load_model

class DeepfakeForensicValidator:

    def __init__(self, model_path='weights/mesonet_dashcam_v2.h5'):

        self.model = load_model(model_path)

        self.frame_skip = 5 # Analyze every 5th frame for temporal
efficiency

        self.confidence_threshold = 0.85

    def extract_and_preprocess(self, video_path):

        cap = cv2.VideoCapture(video_path)

        frames = []

        count = 0
```

```
        while cap.isOpened():
            ret, frame = cap.read()
            if not ret:
                break
            if count % self.frame_skip == 0:
                # Resize to expected MesoNet input (256x256)
                resized = cv2.resize(frame, (256, 256))
                # Normalize pixel values
                normalized = resized.astype('float32') / 255.0
                frames.append(normalized)
            count += 1
        cap.release()
        return np.array(frames)

    def validate_authenticity(self, video_path):
        frames = self.extract_and_preprocess(video_path)
        if len(frames) == 0:
            return {"status": "error", "message": "Corrupted media
file"}

        # Perform batch prediction
```

```
        predictions = self.model.predict(frames)

        # Calculate mean authenticity score across video timeline
        mean_score = np.mean(predictions)

        is_authentic = bool(mean_score > self.confidence_threshold)

        return {
            "is_authentic": is_authentic,
            "authenticity_score": float(mean_score),
            "frames_analyzed": len(frames),
            "verdict": "CLEARED" if is_authentic else "DEEPFAKE_DETECTED"
        }
```

APPENDIX C: VISION-LANGUAGE MODEL PIPELINE (Liyanage R.L.N.L)

C.1 YOLOv11 Semantic Extractor and Kimi-K2.5 API Integration

This script demonstrates how YOLOv11 tracks a vehicle crossing a solid line, crops the sequence, and prompts the VLM for legal classification.

```
import cv2
import requests
from ultralytics import YOLO
```

```
class SemanticViolationDetector:

    def __init__(self, yolo_weights='yolov11x.pt', api_key='KIMI_API_KEY'):

        self.yolo = YOLO(yolo_weights)

        self.vlm_endpoint = "https://api.kimi.ai/v1/vision/classify"

        self.headers = {"Authorization": f"Bearer {api_key}"}

    def detect_trajectory_violation(self, frame_sequence, target_id):

        # Base prompt mapping physical movement to legal statute

        system_prompt = """

        You are an expert Sri Lankan Traffic Police Analyst.

        Analyze this sequence of frames. Focus on the vehicle marked with a red bounding box.

        Did this vehicle cross a solid white line to overtake?

        Respond in JSON with 'violation_detected' (boolean) and 'legal_reasoning' (string).

        """

        payload = {

            "model": "kimi-k2.5-vision",

            "messages": [

                {"role": "system", "content": system_prompt},
```

```
                {"role": "user", "content": [
                    {"type":   "image_url",   "image_url":   {"url":
frame_sequence[0]}},
                    {"type":   "image_url",   "image_url":   {"url":
frame_sequence[-1]}}
                ]}
            ]
        }

        try:
            response = requests.post(self.vlm_endpoint, json=payload,
headers=self.headers)
            response.raise_for_status()
            return response.json()
        except requests.exceptions.RequestException as e:
            return {"error": str(e), "violation_detected": False}
```

APPENDIX D: ANPR & OCR SANITIZATION (Rathnayake W.K.D)

D.1 Bounding Box Sorting and Regex Formatting for Sri Lankan Plates

Because Sri Lankan plates stack regional prefixes, standard left-to-right OCR fails. This algorithm sorts bounding boxes topologically and sanitizes the output.

```
import re
```

```
def sort_ocr_bounding_boxes(ocr_results):
    """
    Sorts OCR bounding boxes top-to-bottom, then left-to-right to handle
    stacked Sri Lankan regional prefixes (e.g., WP \n CBA-1234).
    """
    # result format: ([[x1,y1], [x2,y2], [x3,y3], [x4,y4]], text, confidence)
    # Sort primarily by the Y-coordinate (top to bottom)
    ocr_results.sort(key=lambda x: x[0][0][1])

    lines = []
    current_line = []
    previous_y = ocr_results[0][0][0][1]
    y_tolerance = 15 # pixels

    for result in ocr_results:
        current_y = result[0][0][1]
        if abs(current_y - previous_y) > y_tolerance:
            # Sort the completed line left-to-right based on X-coordinate
            current_line.sort(key=lambda x: x[0][0][0])
            lines.append(current_line)
```

```
            current_line = []
        current_line.append(result)
        previous_y = current_y

    if current_line:
        current_line.sort(key=lambda x: x[0][0][0])
        lines.append(current_line)

    # Flatten and extract text
    final_text = " ".join([item[1] for line in lines for item in line])
    return final_text

def sanitize_sri_lankan_plate(raw_text):
    """
    Applies regex to fix common OCR hallucinations specific to SL plates.
    """
    cleaned = raw_text.upper().replace(" ", "").replace("-", "")

    # Fix common letter/number confusions
    confusions = {'O': '0', 'I': '1', 'Z': '2', 'S': '5', 'B': '8'}
```

```
    # Standard format: 2-3 Letters followed by 4 numbers (e.g., CBA1234 or WPCAA1234)

    match = re.search(r'([A-Z]{2,5})(\d{4})', cleaned)

    if match:

        letters = match.group(1)

        numbers = match.group(2)

        # Apply corrections to the number part only

        for char, num in confusions.items():

            numbers = numbers.replace(char, num)

        return f"{letters}-{numbers}"

    return "UNREADABLE_MANUAL_REVIEW"
```

APPENDIX E: BACKEND DETERMINISTIC ENGINE (Hendawitharana H.W.K.P)

E.1 FastAPI Route and PostgreSQL Ledger Execution

```
from fastapi import APIRouter, Depends, HTTPException

from sqlalchemy.orm import Session

from models import db_models, schemas

from config.database import get_db

router = APIRouter(prefix="/api/v1/enforcement")
```

```
# Hardcoded deterministic legal statutes (Sri Lankan Motor Traffic Act)

VIOLATION_DICTIONARY = {

    "OVERTAKING_SOLID_LINE":  {"base_points":  3,  "base_fine_lkr": 5000.00},

    "RECKLESS_DRIVING":    {"base_points":    6,    "base_fine_lkr": 15000.00},

    "RED_LIGHT_VIOLATION":   {"base_points":   4,   "base_fine_lkr": 10000.00}

}

@router.post("/adjudicate", response_model=schemas.AdjudicationResponse)

def execute_deterministic_penalty(payload: schemas.ViolationPayload, db: Session = Depends(get_db)):

    # 1. Fetch Legal Dict

    statute = VIOLATION_DICTIONARY.get(payload.violation_type)

    if not statute:

        raise HTTPException(status_code=400, detail="Violation type not recognized in legal dictionary.")

    # 2. Check Repeat Offender Multiplier
```

```
    past_offenses = db.query(db_models.DriverRecord).filter(

            reward_amount_lkr=split["citizen_reward_25"]
        )

        db.add(new_record)
        db.add(new_reward_ledger)
        db.commit() # Atomic commit for transactional integrity

        # Trigger async Gemini Email notification

        return {"status": "SUCCESS", "fine": final_fine, "split": split}

    except Exception as e:
        db.rollback()
```

```
        raise    HTTPException(status_code=500,    detail=f"Database
Transaction Failed: {str(e)}")
```

APPENDIX F: RESTFUL API SWAGGER DOCUMENTATION

F.1 Video Ingestion and Authenticity API

- **Endpoint:** /api/v1/video/upload
- **Method:** POST
- **Content-Type:** multipart/form-data
- **Description:** Accepts raw citizen dashcam footage and pipes it into the CNN/MesoNet validation queue.
- **Success Response (200 OK):**

```
{
  "upload_id": "vid_9948274a",
  "status": "PROCESSING",
  "authenticity_check": "PENDING",
  "timestamp": "2026-05-12T08:14:22Z"
}
```

F.2 Semantic Violation Query API

- **Endpoint:** /api/v1/detect/violation
- **Method:** POST
- **Request Payload:**

```
{
  "yolo_track_id": 104,
```

```
  "frame_sequence_urls": [
    "s3://bucket/temp/frame_104_start.jpg",
    "s3://bucket/temp/frame_104_end.jpg"
  ],
  "detected_environment": "NIGHT_VISION"
}
```

F.3 Backend Deterministic Adjudication API (Hendawitharana H.W.K.P)

- **Endpoint:** /api/v1/enforcement/adjudicate
- **Method:** POST
- **Success Response (201 Created):**

```
{
  "adjudication_id": "adj_55912",
  "violator_plate": "WP-CBA-1234",
  "infraction_type": "SOLID_LINE_CROSSING",
  "financial_split": {
    "total_fine_lkr": 5000.00,
    "government_tax_lkr": 3000.00,
    "citizen_reward_lkr": 1250.00,
    "system_maintenance_lkr": 750.00
  },
  "notification_status": "GEMINI_EMAIL_DISPATCHED"
```

```
}
```

APPENDIX G: RELATIONAL DATABASE SCHEMA (SQL)

G.1 PostgreSQL Database Initialization Scripts

The following Data Definition Language (DDL) scripts define the strict, relational constraints of the GoodRoad deterministic backend, ensuring all driver profiles, verified violations, and financial splits maintain ACID compliance.

```
-- Create Enum for Violation Types to prevent arbitrary data entry

CREATE TYPE violation_category AS ENUM (

    'OVERTAKING_SOLID_LINE',

    'RECKLESS_DRIVING',

    'RED_LIGHT_VIOLATION',

    'ILLEGAL_U_TURN'

);

-- Table: Driver Profiles

CREATE TABLE IF NOT EXISTS drivers (

    driver_id UUID PRIMARY KEY DEFAULT gen_random_uuid(),

    plate_no VARCHAR(15) UNIQUE NOT NULL,

    owner_name VARCHAR(100) NOT NULL,

    email VARCHAR(255) UNIQUE NOT NULL,

    vehicle_type VARCHAR(50),
```

```
    total_penalty_points INT DEFAULT 0,
    created_at TIMESTAMP WITH TIME ZONE DEFAULT CURRENT_TIMESTAMP
);

-- Table: Verified Violations (The Source of Truth)
CREATE TABLE IF NOT EXISTS verified_violations (
    violation_id UUID PRIMARY KEY DEFAULT gen_random_uuid(),
    driver_id UUID REFERENCES drivers(driver_id) ON DELETE CASCADE,
    reporter_id UUID NOT NULL, -- Links to citizen who uploaded
    violation_type violation_category NOT NULL,
    confidence_score DECIMAL(4,3) NOT NULL CHECK (confidence_score >
0.85),
    video_evidence_url TEXT NOT NULL,
    plate_crop_url TEXT NOT NULL,
    timestamp_of_infraction TIMESTAMP WITH TIME ZONE NOT NULL,
    processed_at TIMESTAMP WITH TIME ZONE DEFAULT CURRENT_TIMESTAMP
);

-- Table: Financial Ledger (60/25/15 Split)
CREATE TABLE IF NOT EXISTS financial_ledger (
    transaction_id UUID PRIMARY KEY DEFAULT gen_random_uuid(),
    violation_id UUID REFERENCES verified_violations(violation_id),
```

```
    total_fine_lkr DECIMAL(10,2) NOT NULL,
    gov_tax_lkr DECIMAL(10,2) NOT NULL,
    citizen_reward_lkr DECIMAL(10,2) NOT NULL,
    system_maintenance_lkr DECIMAL(10,2) NOT NULL,
    payment_status VARCHAR(20) DEFAULT 'PENDING',
    executed_at TIMESTAMP WITH TIME ZONE DEFAULT CURRENT_TIMESTAMP
);

-- Indexing for high-speed deterministic querying
CREATE INDEX idx_driver_plate ON drivers(plate_no);
CREATE INDEX idx_violation_date ON verified_violations(timestamp_of_infraction);
```

APPENDIX H: DOCKER DEPLOYMENT CONFIGURATIONS

H.1 FastAPI Backend Dockerfile

This configuration containerizes the deterministic enforcement engine, ensuring it runs identically across local development and production municipal servers.

```
# Stage 1: Build environment
FROM python:3.11-slim as builder
WORKDIR /app
COPY requirements.txt .
RUN pip install --user --no-cache-dir -r requirements.txt
```

```
# Stage 2: Production execution

FROM python:3.11-slim

WORKDIR /app

# Copy installed dependencies from builder

COPY --from=builder /root/.local /root/.local

ENV PATH=/root/.local/bin:$PATH

# Copy application code

COPY ./src /app/src

COPY ./config /app/config

# Expose API gateway port

EXPOSE 8000

# Run Uvicorn server for asynchronous FastAPI

CMD  ["uvicorn",  "src.main:app",  "--host",  "0.0.0.0",  "--port",
"8000", "--workers", "4"]
```

APPENDIX I: DATA DICTIONARY

I.1 Financial Ledger Table Definitions

The strict mapping of data types required for the automated penalty algorithm.

Column Name	Data Type	Constraint	Description
transaction_id	UUID	PRIMARY KEY	Unique identifier for the transaction.
violation_id	UUID	FOREIGN KEY	Links to the specific verified media evidence.
total_fine_lkr	DECIMAL(10,2)	NOT NULL	The base legal fine multiplied by the repeat-offense multiplier.
gov_tax_lkr	DECIMAL(10,2)	NOT NULL	Exactly 60% of total_fine_lkr.
citizen_reward_lkr	DECIMAL(10,2)	NOT NULL	Exactly 25% of total_fine_lkr.
system_maintenance_lkr	DECIMAL(10,2)	NOT NULL	Exactly 15% of total_fine_lkr.
payment_status	VARCHAR(20)	DEFAULT 'PENDING'	Tracks if the violator has settled the digital ticket.
